1. Executive Summary

Employee retention is an important workforce challenge because employee turnover can affect workforce stability, organizational knowledge, recruitment effort, and long-term workforce capability. However, an overall termination rate alone does not explain where retention pressure is concentrated or which employee groups may require further investigation.

This project analyzes workforce retention and career progression patterns using a multi-table Human Resources dataset containing employee, employment action, and performance records. The analysis was developed in **Tableau** and focuses on identifying patterns across workforce stability, termination, tenure, career level, and employee performance.

The project was structured around three key areas:

- **Workforce Stability** — understanding overall workforce composition, tenure distribution, and termination patterns.
- **Retention Pressure** — identifying workforce segments where termination rates appear more concentrated.
- **Career Development & Progression** — examining workforce tenure, career level distribution, and performance patterns among active employees.

The analysis found that employee termination was not evenly distributed across the workforce. Employees with **2–5 years of tenure showed the highest termination rate at 50.0%**, compared with **19.0% among employees with more than five years of tenure**. This makes the mid-tenure workforce an important area for further retention investigation.

The analysis also identified variation in termination patterns across career levels. These differences highlight the importance of segmenting workforce data rather than relying only on an overall termination rate. Career-level and tenure analysis can help identify where retention pressure may be concentrated and where further investigation should be prioritized.

Performance analysis showed that termination patterns varied across performance groups. When performance was analyzed together with tenure, the **2–5 year tenure group consistently showed elevated termination rates across multiple performance ratings**. This suggests that retention pressure within this tenure group should be investigated across a broader employee population rather than focusing only on low-performing employees.

The career development analysis focused on the active workforce and showed that employees were concentrated in longer-tenure groups and across mid-career level bands. Performance ratings across career levels were generally centered around average ratings, providing an additional perspective on the relationship between workforce experience, career position, and performance.

Overall, the project demonstrates that employee turnover should not be viewed as a single workforce-wide issue. Examining termination patterns through dimensions such as **tenure**,

career level, and performance provides a more detailed view of where potential retention pressure exists.

The key conclusion of the analysis is:

Employee turnover is not evenly distributed across the workforce, with the 2–5 year tenure segment showing the strongest retention pressure and requiring deeper investigation.

Overall Recommendation

HR and workforce leaders should prioritize further investigation into employee groups with elevated termination rates, particularly the **2–5 year tenure segment** and career levels showing higher termination patterns.

However, the findings identify **patterns rather than causes**. Additional information such as employee engagement, compensation, promotion history, manager relationships, workload, and exit interview feedback would be needed to understand why employees leave and determine the most appropriate retention actions.

This project demonstrates an end-to-end analytics workflow covering **data preparation, multi-table analysis, Tableau calculations, workforce segmentation, dashboard development, quality assurance, and business-focused interpretation.**

2. Business Scenario & Objectives

Business Scenario

Employee retention is a key workforce concern because high employee turnover can create additional recruitment costs, reduce organizational knowledge, and affect workforce continuity. While an overall termination rate provides a high-level view of employee turnover, it does not identify which workforce groups experience the greatest retention pressure.

The organization requires a clearer view of workforce stability and employee termination patterns. Specifically, HR stakeholders need to understand how retention varies across employee tenure, career levels, and performance ratings.

To address this, an interactive Tableau dashboard was developed using employee, employment action, and performance data. The analysis was designed to move beyond a single workforce-wide turnover metric and instead identify patterns across different employee segments.

The project was organized into three analytical areas:

- **Workforce Stability** — examining overall workforce composition, employee tenure, and termination patterns.
- **Retention Pressure** — identifying where higher termination rates are concentrated across workforce segments.
- **Career Development & Progression** — examining the relationship between tenure, career levels, and employee performance within the active workforce.

The purpose of the analysis was not to determine the exact causes of employee termination. Instead, the goal was to identify patterns and workforce segments that may require further investigation.

Project Objectives

The primary objective of the project was to develop an interactive workforce analytics dashboard that supports the identification of retention patterns and potential areas of workforce risk.

The analysis aimed to:

1. Assess Overall Workforce Stability

Evaluate the size and composition of the workforce by examining:

- Total employees
- Active employees
- Terminated employees
- Overall termination rate
- Employee tenure distribution

2. Identify Where Retention Pressure Is Concentrated

Analyze termination rates across key workforce segments, including:

- Employee tenure
- Career levels
- Performance ratings
- The relationship between performance and tenure

The objective was to identify which employee groups show relatively higher termination rates and should be prioritized for further investigation.

3. Examine Workforce Tenure and Career Distribution

Analyze the composition of the active workforce by examining:

- Workforce distribution by tenure
- Workforce distribution by career level
- Career level segmentation

- Performance distribution across career levels

This provides additional context on the current workforce structure and employee progression.

4. Support More Targeted HR Investigation

Rather than treating employee turnover as a single organization-wide issue, the dashboard was designed to help stakeholders identify specific workforce segments that may require deeper investigation.

The findings can support further analysis into potential factors such as:

- Career development opportunities
- Compensation
- Employee engagement
- Workload
- Management relationships
- Promotion opportunities
- Exit feedback

These factors were not available in the dataset and therefore were not used to establish causal relationships.

Key Business Questions

The project was designed to answer the following questions:

Workforce Stability

- What is the overall composition of the workforce?
- What proportion of employees are active versus terminated?
- How does termination vary across employee tenure?
- Which career levels show higher termination rates?

Retention Pressure

- How does termination vary across employee performance ratings?
- Which combinations of tenure and performance show higher termination rates?
- How does termination timing vary across employee tenure?

Career Development & Progression

- How is the active workforce distributed across tenure groups?
- How is the workforce distributed across career level bands?
- How does performance vary across different career levels?

Expected Business Value

The final dashboard provides HR stakeholders with a structured view of workforce retention patterns through three connected perspectives:

Workforce Stability → Retention Pressure → Career Development & Progression

This structure allows users to begin with a high-level view of workforce stability, identify where retention pressure is more concentrated, and examine the composition of the active workforce across tenure, career level, and performance.

The analysis is intended to support **data-driven investigation and workforce monitoring**, rather than provide definitive explanations for why employees leave.

3. Data & Preparation

Data Source

This project used a Human Resources analytics dataset containing employee, employment action, and performance records. The dataset was structured across multiple tables, allowing the analysis to examine workforce stability and retention patterns from different perspectives.

The primary data tables used in the analysis were:

- **Employee Data** — employee demographic, employment, and career information.
- **Employee Action Data** — employment actions and termination-related records.
- **Performance Data** — employee performance ratings and performance review dates.

The tables were analyzed together in Tableau using their employee identifiers to support workforce-level analysis.

Data Overview

The dataset included information relevant to the following areas:

Employee Information

Employee-level data included fields used to analyze:

- Employee ID
- Employee status
- Career level

- Employment dates
- Workforce tenure

This table served as the primary source for workforce composition and employee segmentation.

Employment Action Information

Employment action data was used to support the analysis of employee events and termination-related timing.

This information was used to examine:

- Employment actions
- Termination records
- Action timing
- Tenure-related termination patterns

Performance Information

The performance table contained employee performance records, including:

- Performance record ID
- Employee ID
- Performance rating
- Performance date

Because employees could have multiple performance records, the analysis used the latest available performance record when examining the current relationship between performance and career level.

Data Preparation

The data preparation process focused on ensuring that the dataset could support consistent workforce calculations and segmentation.

Employee-Level Workforce Analysis

Employee ID was used as the primary identifier for workforce calculations.

Where necessary, **distinct employee counts** were used instead of record counts to prevent employees with multiple related records from being counted more than once.

This was particularly important when analyzing performance data because an employee could have multiple performance records.

Employee Status Validation

Employee status was used to distinguish between:

- Active employees
- Terminated employees

This distinction was important throughout the analysis because different dashboard pages focused on different workforce populations.

For example:

- Workforce stability and retention analysis included employee termination information.
- Career development and progression analysis focused primarily on the **active workforce**.

Tenure Segmentation

Employee tenure was calculated and grouped into categories to make workforce patterns easier to interpret.

Tenure bands were used throughout the analysis to compare workforce stability and retention patterns across different stages of employee experience.

These segments were particularly important because the analysis identified meaningful differences in termination rates across tenure groups.

Career Level Segmentation

Career levels were grouped into broader bands to improve dashboard readability and support higher-level workforce analysis.

The career level bands used were:

- Level 1–5
- Level 6–10
- Level 11–15
- Level 16–20
- Level 21–25
- Level 26–31

This approach provided more detail than grouping all career levels into only a few broad categories while still making the analysis easier to interpret than displaying every individual career level separately.

Performance Rating Preparation

Performance ratings were grouped into descriptive categories:

- 1 — **Low**
- 2 — **Below Avg**
- 3 — **Average**
- 4 — **Above Avg**
- 5 — **High**

For analysis involving the current workforce, the latest available performance record for each employee was used.

This preparation step was important because using all historical performance records could result in the same employee appearing under multiple performance ratings.

By using the latest available performance record, each employee was represented by a single performance rating when analyzing performance distribution across career levels.

Data Quality Considerations

Several validation checks were performed during the dashboard development process.

These included:

- Confirming distinct employee counts.
- Checking employee status filters.
- Validating termination rate calculations.
- Reviewing tenure segmentation.
- Ensuring employees were not duplicated because of multiple performance records.
- Using the latest available performance record for employee-level performance analysis.
- Reviewing null performance values separately from valid performance ratings.

These checks were important to ensure that the dashboard represented employee-level workforce patterns rather than inflated record-level counts.

Preparation Outcome

After preparation and validation, the dataset was structured to support three connected areas of analysis:

1. **Workforce Stability**
2. **Retention Pressure**
3. **Career Development & Progression**

The preparation process ensured that the analysis could move between overall workforce metrics and more detailed employee segmentation while maintaining consistent employee-level calculations.

4. Data Model

Data Model Overview

The analysis was built using a multi-table data structure consisting of employee, employment action, and performance data. Rather than combining all records into a single flat table, the data was maintained as related tables in Tableau.

This approach supported employee-level analysis while preserving the different levels of detail contained in each dataset.

The three primary data areas were:

- **Employee Data** — workforce and career information.
- **Employment Action Data** — employee actions and termination-related records.
- **Performance Data** — employee performance ratings over time.

The employee identifier served as the key field used to connect the different data sources.

Table Relationships

Employee Data

The employee table served as the primary workforce table and contained one record per employee.

It provided the core information used throughout the dashboard, including:

- Employee ID
- Employee status
- Career level
- Employment information
- Tenure-related fields

This table formed the foundation for workforce-level calculations such as total employees, active employees, and terminated employees.

Employment Action Data

The employment action table contained employee action records associated with individual employees.

An employee could have multiple action records, meaning this table could contain more than one record for a single employee.

This data was used to support analysis related to:

- Employment actions
- Termination timing
- Action dates
- Termination-related workforce patterns

Because multiple records could exist for an employee, employee-level calculations required careful use of distinct employee counts.

Performance Data

The performance table contained employee performance records with the following core structure:

Field	Description
PerfID	Unique performance record identifier
EmpID	Employee identifier
Rating	Employee performance rating
Perf Date	Date of the performance record

Employees could have multiple performance records over time.

For this reason, performance analysis required additional logic when examining the current workforce. Using all performance records could result in a single employee appearing under multiple performance ratings.

To address this, the analysis used the **latest available performance record** when evaluating performance distribution across career levels.

Relationship Structure

The data model can be summarized as:

The employee table served as the central workforce dataset, while employment action and performance records provided additional information for more detailed analysis.

Why a Multi-Table Model Was Used

The datasets were not flattened into a single table because the related tables contained different levels of detail.

For example:

- One employee could have multiple employment action records.
- One employee could have multiple performance records.

Combining all tables through a traditional flat join could potentially duplicate employee records and inflate workforce calculations.

Maintaining the data as related tables helped preserve the structure of each dataset while allowing Tableau to combine information when required for analysis.

This approach supported more accurate employee-level calculations, particularly when using:

COUNTD(EmpID)

for workforce metrics and visualizations.

Employee-Level Calculation Logic

Because the project focused primarily on workforce analysis, the employee was treated as the primary unit of analysis.

Where related tables contained multiple records per employee, distinct employee counts were used to reduce the risk of duplicated workforce totals.

For example:

- **Total Employees** → distinct employee count
- **Active Employees** → distinct employee count filtered to active status
- **Terminated Employees** → distinct employee count filtered to terminated status
- **Performance Analysis** → distinct employee count using the latest available performance record

This ensured that dashboard metrics represented employees rather than the total number of records across all related tables.

Data Model Considerations

The multi-table structure required additional validation during analysis.

The main considerations were:

1. **Avoiding duplicate employee counts**
Related action and performance tables could contain multiple records for the same employee.
2. **Using the correct level of detail**
Workforce KPIs were calculated at the employee level, while action and performance analysis used related records only when relevant.

3. **Identifying the latest performance record**

Historical performance records were not appropriate for all workforce visuals because employees could appear under multiple ratings.

4. **Maintaining consistent filtering**

Employee status filters were applied carefully depending on the purpose of each dashboard page.

Data Model Outcome

The final Tableau data model supported analysis across multiple workforce dimensions without relying on a single flattened dataset.

The model allowed the project to combine:

- Workforce composition
- Employee status
- Tenure
- Career level
- Employment actions
- Performance ratings

while maintaining employee-level accuracy through distinct counting and calculated field logic.

Figure 1-- Tableau Data Model

5. Analytical Approach & Tableau Calculations

Analytical Approach

The analysis followed a structured approach designed to move from high-level workforce metrics toward more detailed employee segmentation.

The workflow focused on:

1. Establishing the overall workforce picture.
2. Calculating employee-level retention metrics.
3. Segmenting employees by tenure, career level, and performance.
4. Identifying workforce groups with higher termination rates.
5. Analyzing the active workforce to understand career and performance distribution.

The dashboard was organized around three connected analytical perspectives:

Workforce Stability → Retention Pressure → Career Development & Progression

This structure allowed the analysis to first establish the overall workforce situation before examining where retention pressure appeared more concentrated and how the active workforce was distributed.

Key Tableau Calculations

Employee Counts

Because related tables could contain multiple records for the same employee, workforce metrics were primarily based on distinct employee counts.

`COUNTD([EmpID])`

This ensured that each employee was counted once when calculating workforce totals.

Distinct employee counts were used throughout the project to support metrics such as:

- Total Employees
- Active Employees
- Terminated Employees
- Workforce distribution
- Performance distribution

Termination Rate

The termination rate was used as the primary retention metric.

The calculation compared terminated employees with the total employee population within the selected segment.

Conceptually:

$$\text{Termination Rate} = \frac{\text{Terminated Employees}}{\text{Total Employees}}$$

This calculation allowed termination rates to be compared across:

- Tenure groups
- Career levels
- Performance ratings
- Other workforce segments

Using a rate rather than termination counts alone was important because workforce groups varied in size.

Tenure Segmentation

Employee tenure was grouped into categories to support easier comparison across workforce stages.

Tenure segmentation was used to answer questions such as:

- How is the workforce distributed by tenure?
- Which tenure groups have higher termination rates?
- How does performance-related retention pressure vary by tenure?

The tenure analysis identified the **2–5 year employee group** as an important segment for further investigation because it showed the highest termination rate in the workforce stability analysis.

Career Level Bands

Career levels were grouped into six bands to provide a clearer view of workforce distribution.

The bands were:

- Level 1–5
- Level 6–10
- Level 11–15
- Level 16–20
- Level 21–25
- Level 26–31

The calculation followed a grouped structure similar to:

```

IF [Career Level] <= 5 THEN
    "Level 1–5"

ELSEIF [Career Level] <= 10 THEN
    "Level 6–10"

ELSEIF [Career Level] <= 15 THEN
    "Level 11–15"

ELSEIF [Career Level] <= 20 THEN
    "Level 16–20"

ELSEIF [Career Level] <= 25 THEN
    "Level 21–25"

ELSE
    "Level 26–31"
END

```

This segmentation provided more detail than broad career-level categories while maintaining readability within the dashboard.

Performance Rating Bands

Performance ratings were converted into descriptive categories to make the dashboard easier to interpret.

The rating bands were:

Rating	Performance Band
1	Low
2	Below Avg
3	Average
4	Above Avg
5	High

This allowed performance patterns to be displayed using meaningful labels rather than only numerical ratings.

Latest Performance Record Logic

The performance dataset could contain multiple records for the same employee. This created an important analytical challenge because using all historical performance records could cause an employee to appear under multiple performance ratings.

To address this, the analysis identified the latest available performance record for each employee.

The project used a latest performance date calculation to determine the most recent performance review associated with each employee.

The latest performance record logic was structured as:

```
IF DATE([Perf Date]) = [Latest Performance Date] THEN  
    [Performance Rating]  
END
```

This ensured that the employee's most recent available rating was used when analyzing the current workforce.

A corresponding performance rating band was then created from the latest performance record:

```
IF [Latest Performance Record] = 1 THEN  
    "1 - Low"  
  
ELSEIF [Latest Performance Record] = 2 THEN  
    "2 - Below Avg"  
  
ELSEIF [Latest Performance Record] = 3 THEN  
    "3 - Average"  
  
ELSEIF [Latest Performance Record] = 4 THEN  
    "4 - Above Avg"  
  
ELSEIF [Latest Performance Record] = 5 THEN  
    "5 - High"  
  
END
```

This approach was particularly important for the **Performance Distribution by Career Level** analysis.

Active Workforce Filtering

The third dashboard focused on career development and workforce progression among current employees.

For this reason, the relevant visuals were filtered to:

Employee Status = Active

This ensured that tenure, career level, and performance distributions represented the current workforce rather than employees who had already left the organization.

Analytical Validation

During dashboard development, several checks were performed to validate calculations and visual outputs.

These included:

Employee Count Validation

Distinct employee counts were reviewed to prevent duplication caused by multiple related records.

Performance Record Validation

Historical performance records were separated from latest performance analysis to avoid employees appearing under multiple ratings.

Percentage Validation

Performance distributions were checked to ensure percentages represented the intended employee segment and calculation direction.

Filter Validation

Employee status filters and dashboard interactions were reviewed to confirm that visuals responded appropriately.

Visual Validation

Dashboard charts were reviewed to ensure that titles, labels, categories, and key findings matched the underlying analysis.

Analytical Approach Outcome

The calculations and segmentation logic allowed the project to move beyond basic workforce reporting.

The analysis provided a structured way to examine:

- Overall workforce stability
- Employee termination patterns
- Retention pressure by tenure and performance
- Career-level workforce distribution
- Performance patterns across career levels

The calculations were designed to support **employee-level analysis and pattern identification**, while avoiding unsupported conclusions about why employees leave.

The next section applies this analytical approach to the completed dashboards and presents the key findings from each stage of the analysis.

6. Dashboard Analysis & Key Findings

The final Tableau dashboard consists of three pages designed to analyze workforce stability, retention pressure, and career development.

Dashboard 1 — Workforce Stability

The first dashboard provides an overview of workforce composition and employee termination patterns.

The analysis examines:

- Total, active, and terminated employees
- Overall termination rate
- Workforce distribution by tenure
- Termination rate by tenure
- Termination rate by career level

Key Finding

Employees with **2–5 years of tenure recorded the highest termination rate at 50.0%**, compared with **19.0% among employees with more than five years of tenure**.

This identifies the mid-tenure workforce as an important area for further retention investigation.

Figure 2— Workforce Stability Dashboard

Dashboard 2 — Retention Pressure

The second dashboard examines where termination patterns are more concentrated across performance and tenure groups.

The analysis includes:

- Termination rate by performance
- Termination rate by performance and tenure
- Tenure at termination

The performance × tenure analysis showed that employees with 2–5 years of tenure consistently recorded elevated termination rates across multiple performance ratings.

Key Finding

The elevated termination pattern among mid-tenure employees was visible across multiple performance groups, suggesting that retention pressure should not be investigated only among low-performing employees.

Figure 3— Retention Pressure Dashboard

Dashboard 3 — Career Development & Progression

The final dashboard focuses on the composition of the active workforce.

The analysis examines:

- Workforce distribution by tenure
- Workforce distribution by career level

- Performance distribution across career levels

The active workforce was largely composed of longer-tenured employees and was concentrated across mid-career level bands. Performance ratings across career levels were generally centered around the **Average** rating.

Key Finding

The active workforce is largely composed of longer-tenured, mid-career employees, with performance ratings generally centered around the Average rating.

Figure 4— Career Development & Progression Dashboard

Overall Key Findings

The analysis identified several important workforce patterns:

1. Mid-Tenure Employees Show the Highest Retention Pressure

Employees with **2–5 years of tenure** showed the highest termination rate and consistently elevated termination patterns across performance groups.

2. Retention Patterns Vary Across Workforce Segments

Termination rates differed across tenure groups, career levels, and performance ratings, showing that workforce segmentation provides more insight than an overall termination rate alone.

3. Performance Does Not Fully Explain Retention Pressure

The elevated termination pattern among mid-tenure employees appeared across multiple performance ratings, indicating that performance alone does not explain the observed retention pattern.

4. The Active Workforce Is Concentrated Among Longer-Tenured and Mid-Career Employees

The current workforce contains a substantial number of longer-tenured employees and is distributed primarily across mid-career level bands.

Summary

The most consistent finding across the analysis was the elevated termination rate among employees with **2–5 years of tenure**.

The findings identify workforce segments that require further investigation but do not establish the underlying causes of employee termination.

7. Recommendations

Based on the findings from the workforce retention analysis, the following recommendations are proposed.

1. Prioritize the 2–5 Year Tenure Group

Employees with **2–5 years of tenure showed the highest termination rate at 50.0%** and consistently elevated termination patterns across multiple performance groups.

HR should prioritize this employee segment for deeper investigation to better understand the factors contributing to employee exits.

Potential areas to investigate include:

- Career development opportunities
- Compensation and benefits
- Promotion opportunities
- Employee engagement
- Workload
- Manager relationships

2. Review Career Levels with Higher Termination Rates

Termination rates varied across career levels, suggesting that retention pressure is not evenly distributed throughout the organization.

HR should identify career levels with elevated termination rates and investigate whether specific workforce conditions are contributing to employee exits.

3. Monitor Retention Beyond Performance Ratings

The analysis showed that elevated termination patterns among mid-tenure employees occurred across multiple performance groups.

This suggests that retention strategies should not focus only on low-performing employees. HR should monitor turnover patterns across the broader workforce.

4. Strengthen Ongoing Workforce Monitoring

The dashboard can be used as a starting point for ongoing workforce monitoring.

Regularly tracking termination patterns across:

- Tenure
- Career level
- Performance

can help identify emerging retention risks and workforce changes earlier.

Recommendation Summary

The highest priority should be to investigate the **2–5 year tenure segment**, as this group showed the strongest and most consistent retention pressure across the analysis.

However, additional employee data and qualitative feedback should be used before implementing specific retention interventions.

8. Limitations & Next Steps

Limitations

While the analysis identifies meaningful workforce patterns, several limitations should be considered.

Limited Information on Employee Exit Drivers

The dataset does not include information such as:

- Employee engagement
- Compensation
- Workload
- Manager relationships
- Promotion history
- Exit interview feedback

As a result, the analysis can identify **where retention pressure may exist**, but it cannot determine **why employees leave**.

Patterns Do Not Establish Causation

Higher termination rates among specific tenure, career level, or performance groups should not be interpreted as proof that these factors caused employee termination.

The findings highlight relationships and patterns that require further investigation.

Performance Analysis Uses the Latest Available Record

Employees may have multiple historical performance records. To avoid counting employees under multiple performance ratings, the latest available performance record was used for workforce performance analysis.

This provides a current performance view but does not capture changes in employee performance over time.

Dataset Scope

The analysis is based on the available dataset and should be interpreted within its specific context.

Additional workforce and employee experience data would be required before making broader conclusions or implementing targeted retention interventions.

Next Steps

Future analysis could include:

1. Investigate Employee Exit Drivers

Combine the retention analysis with additional information such as employee engagement surveys, compensation data, promotion history, and exit interviews.

2. Analyze Retention Over Time

If historical workforce snapshots become available, retention trends could be tracked over time to identify whether termination patterns are improving or worsening.

3. Analyze Career Progression

Additional data on promotions and career movement could help evaluate how employee progression relates to retention.

4. Expand Workforce Segmentation

Future analysis could include dimensions such as department, location, manager, or job role to identify more specific areas of retention pressure.

Summary

The current analysis provides a strong starting point for identifying workforce segments that may require attention. The next step is to combine these findings with additional employee and organizational data to better understand the underlying drivers of employee turnover.

9. Conclusion

This project analyzed workforce retention and career progression using a multi-table Human Resources dataset and an interactive Tableau dashboard.

The analysis examined workforce stability, retention pressure, employee tenure, career levels, and performance patterns. By moving beyond a single overall termination rate, the project identified how retention patterns varied across different workforce segments.

The most consistent finding was the elevated termination rate among employees with **2–5 years of tenure**. This pattern was observed in both the overall tenure analysis and the performance × tenure analysis, making the mid-tenure workforce the primary area for further retention investigation.

The analysis also showed that termination patterns varied across career levels and performance groups. This demonstrates the value of workforce segmentation when identifying potential retention risks.

The final dashboard was structured across three connected areas:

- **Workforce Stability** — establishing the overall workforce and termination picture.
- **Retention Pressure** — identifying where elevated termination patterns are concentrated.
- **Career Development & Progression** — examining the composition of the active workforce across tenure, career level, and performance.

Overall, the project demonstrates how Tableau can be used to transform multi-table HR data into an interactive analytical tool that supports workforce monitoring and business investigation.

The findings should not be interpreted as proof of why employees leave. Instead, they provide a starting point for identifying workforce segments that require deeper investigation.

The key value of the analysis is not only identifying how many employees leave, but understanding where retention pressure is most concentrated and where HR should focus further investigation.
